The entity framework is a set of interfaces, classes and methods that provide the fundamental features of an object-relational mapping framework. The functionality is based on Entity Framework 4.0 Beta 1. Entity Framework extends and augments the functionality of the ADO.NET Model designer. Entity Framework enables a new way of creating and accessing model objects that are part of a distributed object framework, but are designed to be mapped to a relational database. This enables developers to create high-performance applications using the ADO.NET object model, and generate persistence logic on the fly. Entity Framework improves the model object features of the ADO.NET Model designer. The ADO.NET model designer has always provided a powerful way to develop a model object graph, however with Entity Framework the developer can leverage the full power of LINQ to SQL, LINQ to Entities and LINQ to NHibernate. The model designer has been extended to support the creation of views that represent the persisted entities and their associations. This enables faster disconnected operations, querying for entities by their views, and navigation properties that point to a "virtual entity". The user of the Entity Framework is not required to write any persistent logic. This is a new implementation of the current Entity Framework model designer, rather than a new designer. Although this is new, it is still based on the existing Entity Framework classes and interfaces, just with some new features. We expect that the Entity Framework will be stable and complete when the Beta 1 release of .NET Framework 4.0 is released. The Entity Framework will be shipped as part of .NET Framework 4.0. Entity Framework includes entity types that define the relationships between model objects. These relationships are mapped to the database through associations. Associations are defined by two classes: one primary and one secondary. The primary class is responsible for defining the foreign key for the relationship. The second class is used to define the value of the relationship. It is called the "association" class. The associations that are defined on an entity type are persisted and cached, just as the entities themselves. In addition, associations that are involved in navigations can be cached and reused. When an entity is deleted, the association cache is used to remove the association that represents the foreign key for the relationship. In Entity Framework the concept of an entity set has been replaced with the concept of an object graph. This means that multiple instances of a model type can exist within a single graph. In the current implementation an entity graph may contain

The behaviour of the generated code has not changed. This includes lazy loading, loading child collections and additional methods to create properties. What is new? The following changes have been introduced to Entity Framework 4.0 in this release. Change in Version of Entity Framework: This release of Entity Framework 4.0 includes the code generation for the beta 1 release of Entity Framework 4.0. What has been fixed in 4.0? The following changes have been introduced in this release of Entity Framework 4.0. Bugs Fixed in Entity Framework 4.0 - Fix for Entity Framework generating more than one constructor method in a derived entity, and for this constructor method to have parameter properties of type dynamic. - Fix for LINQ to Entities QueryExpression throwing "LINQ to Entities queries can contain only Simple Expression" - Fix for Fixing LINQ to Entities generated into sub-entities. - Fix for preventing Entity Framework from generating too many changesets on an UPDATE. - Fix for preventing Entity Framework from generating too many changesets on a delete. - Fix for EF context not caching before automatic updates on an object graph. - Fix for LINQ to Entities having problems with a duplicated ON clause in an UPDATE. - Fix for creating an EntitySet in some cases in Entity Framework 4.0 Beta 1 - Fix for preventing a cycle in EF context re-creation in the case of PropertyChanging. - Fix for EF context preventing updates to navigation properties. - Fix for problems updating related collections of an entity. - Fix for preventing EF context recreating an object graph after an UPDATE. - Fix for preventing Entity Framework 4.0 Beta 1 context recreating an object graph after an UPDATE. - Fix for not caching object graphs that have EF properties that are frozen. - Fix for.NET 3.5 support and compiler warnings on LINQ to Ent 1d6a3396d6

Key features The following sections provide a description of the key new features of Entity Framework 4.0 Beta 1. Microsoft SQL Server 2008 SQL Server 2008 is Microsoft's new relational database management system that is the next generation of SQL Server. SQL Server 2008 brings a number of improvements, such as dynamic data, online indexing and data compression. A new feature called the "LINQ to SQL" query language and integration is also included in SQL Server 2008. This new language enables you to create lightweight business objects, data access layers (DAL), and data models that can be compatible with a variety of technologies. Data modeling Entity Framework 4.0 Beta 1 includes support for Microsoft SQL Server 2008's new features that enhance its data modeling capabilities, including: Composite primary key (Cpk) The new features allow you to define a composite primary key that can be automatically generated by the modeler. This improves the generated SQL and greatly reduces the number of code required to populate the primary key, foreign keys, and other elements of the database. The composite primary key is represented by a table that has two foreign keys and one primary key that references the first table and one of the foreign keys. Figure 1 shows an example of a composite primary key. Figure 1: A composite primary key Note: Composite primary keys are implemented using views in SQL Server 2005. With the new features, the modeler can create a model that can be automatically generated with the following simple configuration. Table1: table1 Table1_ID Foreign Key to Table2_ID
